2 # formatting
3
4 #%%
5 import pandas as pd
6
7
8 #%%
9 # Mapping lets you format an entire DataFrame
10 file = "Resources/sample_data.csv"
11 file_df = pd.read_csv(file)
12 file_df.head()
13
14
15 #%%
16 # Use Map to format all the columns
17 # -----
18 # Format is almost akin to concatenating strings. Whatever is outside of the
19 # curly brackets is added before/after the initial value which is modified
20 # by whatever is contained within the curly brackets.
21 #
22 # "${:.2f}" converts values into a typical dollar format. This places a dollar
23 # sign before the value which has been rounded to two decimal points.
24 # Likewise "{:,}" will split a number up so that it uses comma notation.
25 # For example: the value 2000 would become 2,000 using this format string
26 #
27 # Formatting only really works once and – can also change the datatype of a
28 # column (to string => object) – will return errors if the same code is run
29 # multiple times without restarting the kernel. This is because, depending on
30 # what the value is being formatted to – i.e., it's impossible to apply a 2
31 # floating-point format to a string.
32 # For this reason apply formatting near the end of an application
33 # -----
34 file_df["avg_cost"] = file_df["avg_cost"].map("${:.2f}".format)
35 file_df["population"] = file_df["population"].map("{:,}".format)
36 file_df["other"] = file_df["other"].map("${:.2f}".format)
37 file_df.head()
38
39
40 #%%
41 # Mapping has changed the datatypes of the columns to strings
42 file_df.dtypes
